## Problem 1.1

We have 2 opaque bags, each containing 2 balls. One bag has 2 black balls and the other has a black and a white ball. You pick a bag at random and then pick one of the balls in that bag at random. When you look at the ball it is black. You now pick the second ball from that same bag. What is the probability that this ball is also black? [Hint: Use Bayes' Theorem: P[AandB] = P[A|B]P[B] = P[B|A]P[A].]

$$P(A|B) = \frac{P(A)P(B|A)}{P(B)}$$

- $B_A$  the event that bag A was selected
- $B_B$  the event that bag B was selected
- $k_A$  the event that a black ball from bag A was selected
- $k_B$  the event that a black ball from bag B was selected
- $k_1$  the event that a black ball was selected on the first selection
- $k_2$  the event that a black ball was selected on the second selection

$$k_{1} = B_{A}k_{A} + B_{B}k_{B} = \frac{1}{2} \cdot 1 + \frac{1}{2} \cdot \frac{1}{2} = \frac{1}{2} \cdot \frac{1}{4} = \frac{3}{4}$$

$$P(B_{A}|k_{1}) = \frac{P(B_{A} \cap k_{1})}{P(k_{1})} = \frac{P(k_{1}|B_{B})P(B_{A})}{P(k_{1})}$$

$$P(B_{B}|k_{1}) = \frac{P(B_{B} \cap k_{1})}{P(k_{1})} = \frac{P(k_{1}|B_{B})P(B_{B})}{P(k_{1})}$$

$$P(k_{1}|B_{A}) = \frac{1}{2} \cdot 1 = \frac{1}{2}$$

$$P(k_{1}|B_{B}) = \frac{1}{2} \cdot \frac{1}{2} = \frac{1}{4}$$

$$P(B_{A}) = \frac{1}{2}$$

$$P(B_{A}) = \frac{1}{2}$$

$$P(k_{1}) = \frac{3}{4}$$

$$P(B_{A}|k_{1}) = \frac{P(k_{1}|B_{A})P(B_{A})}{P(k_{1})} = \frac{\frac{1}{2} \cdot \frac{1}{2}}{\frac{3}{4}} = \frac{\frac{1}{4}}{\frac{3}{4}} = \frac{1}{3}$$

$$P(B_{B}|k_{1}) = \frac{P(k_{1}|B_{B})P(B_{B})}{P(k_{1})} = \frac{\frac{1}{4} \cdot \frac{1}{2}}{\frac{3}{4}} = \frac{\frac{1}{8}}{\frac{3}{4}} = \frac{4}{24} = \frac{1}{6}$$

$$P(k_{2}) = P(k_{1}|B_{B})P(k_{B}) + P(B_{B}|k_{1})P(k_{B}) = \frac{1}{3} \cdot 1 + \frac{1}{6} \cdot \frac{1}{2} = \frac{1}{3} + \frac{1}{12} + \frac{4}{12} + \frac{1}{12} = \frac{5}{12}$$

## Problem 1.2

Consider the perceptron in two dimensions:  $h(x) = sign(w^{\mathsf{T}}x)$  where  $w = [w_0, w_1, w_2]$  and  $x = [1, x_1, x_2]$ . Technically, x has three coordinates, but we call this perceptron two-dimensional because the first coordinate is fixed at 1.

(a) Show that the regions on the plane where h(x) = +1 and h(x) = -1 are separated by a line. If we express this line by the equation  $x_2 = ax_1 + b$ , what are the slope a and intercept b in terms of  $w_0$ ,  $w_1$ ,  $w_2$ ?

$$w^{\mathsf{T}}x = 0$$

$$\implies w_0 x_0 + w_1 + x_1 + w_2 x_2 = 0$$

$$\implies w_2 x_2 = -w_1 x_1 - w_0 x_0 = -w_1 x_1 - x_0$$

$$\implies x_2 = -\frac{w_1}{w_2} x_2 - \frac{w_0}{w_2}$$

$$a = -\frac{w_1}{w_2}$$

$$b = -\frac{w_0}{w_2}$$

(b) Draw a picture for the cases w = [1, 2, 3] and w = -[1, 2, 3].

In more than two dimensions, the +1 and -1 regions are separated by a hyperplane, the generalization of a line.

#### Problem 1.3

Prove that the PLA eventually converges to a linear separator for separable data. The following steps will guide you through the proof. Let  $w^*$  be an optimal set of weights (one which separates the data). The essential idea in this proof is to show that the PLA weights w(t) get "more aligned" with  $w^*$  with every iteration. For simplicity, assume that w(0) = 0.

- (a) Let  $\rho = \min_{1 \le n \le N} (w^{*\intercal} x_n)$ . Show that  $\rho > 0$ .
- (b) Show that  $w^{\intercal}(t)w^* \geq w^{\intercal}(t-1)w^* + \rho$ , and conclude that  $w^{\intercal}(t) \geq t\rho$ .
- (c) Show that  $||w(t)||^2 \le ||w(t-1)|| + ||w(t-1)||^2$ .

[Hint:  $y(t-1)\cdot(w^\intercal(t-1)x(t-1))\leq 0$  because x(t-1) was misclassified by w(t-1).]

- (d) Show by induction that  $||w(t)||^2 \le tR^2$ , where  $R = \max_{1 \le n \le N} ||x_n||$ .
- (e) Using (b) and (d), show that

$$\tfrac{w^{\mathsf{T}}}{\|w(t)\|^2} w^* \geq \sqrt{t} \cdot \tfrac{\rho}{R},$$

and hence prove that

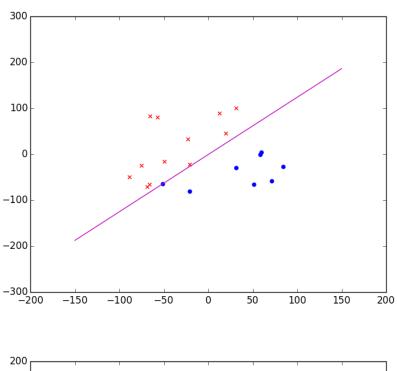

$$\begin{split} &t \leq \frac{R^2 \|w^*\|^2}{\rho^2}.\\ &[\text{Hint: } \frac{w^\intercal(t)w^*}{\|w(t)\| \|w^*\|} \leq 1. \text{ Why?}] \end{split}$$

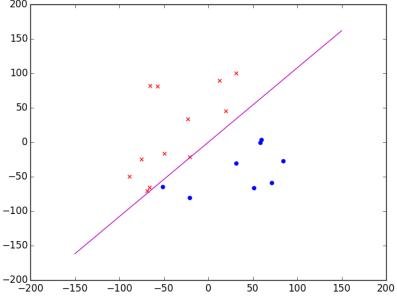

In practice, PLA converges more quickly than the bound  $\frac{R^2\|w^*\|^2}{\rho^2}$  suggests. Nevertheless, because we do not know p in advance, we can't determine the number of iterations to convergence, which does pose a problem if the data is non-separable.

# Problem 1.4

In Exercise 1.4, we use an artificial data set to study the perceptron learning algorithm. This problem leads you to explore the algorithm further with data sets of different sizes and dimensions.

(a) Generate a linearly separable data set of size 20 as indicated in Exercise 1.4. Plot the examples  $(x_n, y_n)$  as well as the target function f on a plane. Be sure to mark the examples from different classes differently, and add labels to the axes of the plot.

(b) Run the perceptron learning algorithm on the data set above. Report the number of updates that the algorithm takes before converging. Plot the

- examples  $(x_n, y_n)$ , the target function f, and the final hypothesis g in the same figure. Comment on whether f is close to g.
- (c) Repeat everything in (b) with another randomly generated data set of size 20. Compare your results with (b).
- (d) Repeat everything in (b) with another randomly generated data set of size 100. Compare your results with (b).
- (e) Repeat everything in (b) with another randomly generated data set of size 1, 000. Compare your results with (b).
- (f) Modify the algorithm such that it takes  $x_n \in \mathbb{R}^n$  instead of  $\mathbb{R}^2$ . Randomly generate a linearly separable data set of size 1,000 with  $x_n \in \mathbb{R}^10$  and feed the data set to the algorithm. How many updates does the algorithm take to converge?
- (g) Repeat the algorithm on the same data set as (f) for 100 experiments. In the iterations of each experiment, pick x(t) randomly instead of deterministically. Plot a histogram r the number of updates that the algorithm takes to converge.
- (h) Summarize your conclusions with respect to accuracy and running time as a function of N and d.
